Electron neutrino and antineutrino appearance in the full MINOS data sample

arXiv:1301.4581 [hep-ex]
Selected candidate electron neutrino and antineutrino events

The reconstructed energy distributions for three ranges of the LEM selection variable. The plots on the left correspond to data collected in the neutrino beam mode. The plots on the right correspond to data collected in the antineutrino beam mode.

Note we are unable to distinguish between $\nu_e$ and $\bar{\nu}_e$ events, so the selected events include a combined contribution of $\nu_e + \bar{\nu}_e$ events.
Results on appearance of electron antineutrinos with $3.3 \times 10^{20}$ POT $\bar{\nu}$ mode running

Exclusion limits based on the selected candidate event distribution in antineutrino mode running

Allowed values are in the color regions
Results on appearance of electron (anti-)neutrinos with $3.3 \times 10^{20}$ POT $\bar{\nu}$ mode running and $10.6 \times 10^{20}$ POT $\nu$ mode running

Exclusion limits based on the selected candidate event distributions for both antineutrino mode running and neutrino mode running

Allowed values are in the color regions
Results on appearance of electron (anti-)neutrinos with $3.3 \times 10^{20}$ POT $\nu$ mode running and $10.6 \times 10^{20}$ POT $\overline{\nu}$ mode running

The resulting values of the likelihood, shown here as $-2\Delta\ln(L)$, from a fit of $\delta$ to our data using constraints from reactor experiments, assuming various values of the mass hierarchy and the sign of $(\theta_{23} - \pi/4)$. The difference is taken with respect to the best fitting solution.
